## ECMAScript 6's new array methods

Labels: [dev](#), [esnext](#), [javascript](#)

Check out my book (free online): “[Exploring ES6](#)”. Updated version of this blog post: chapter “[New Array features](#)”.

This blog post explains what new array methods ECMAScript 6 will bring and how to use them in current browsers.

Note: I'm using the terms *constructor* and *class* interchangeably.

### 1. Class methods

Array has gained methods of its own.

#### 1.1. `Array.from(arrayLike, mapFunc?, thisArg?)`

`Array.from()`'s basic functionality is to convert two kinds of objects to arrays:

- **Array-like objects**, which have a property `length` and indexed elements. Examples include the results of DOM operations such as `document.getElementsByClassName()`.
- **Iterable objects**, whose contents can be retrieved one element at a time. Arrays are iterable, as are ECMAScript's new data structures Map and Set.

The following code is an example of converting an array-like object to an array:

```
let lis = document.querySelectorAll('ul.fancy li');
Array.from(lis).forEach(function (li) {
    console.log(node);
});
```

The result of `querySelectorAll()` is not an array and does not have a `forEach()` method, which is why we need to convert it to an array before we can use that method.

Mapping via `Array.from()`

`Array.from()` is also a convenient alternative to using `map()` generically:

```
let spans = document.querySelectorAll('span.name');

// map(), generically:
let names1 = Array.prototype.map.call(spans, s => s.textContent);

// Array.from():
let names2 = Array.from(spans, s => s.textContent);
```

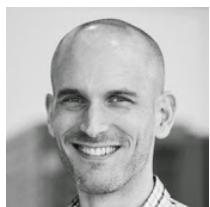

The second parameter of both methods is an [arrow function](#).

In this example, the result of `document.querySelectorAll()` is again an array-like object, not an array, which is why we couldn't invoke `map()` on it. Previously, we converted the array-like object to an array in order to call `forEach()`. Here, we skipped

that intermediate step via a generic method call and via the two-parameter version of `Array.from()`.

### Holes

`Array.from()` ignores holes [3] in arrays, it treats them as if they were undefined elements:

```
> Array.from([0,,2])
[ 0, undefined, 2 ]
```

That means that you can use `Array.from()` to create and fill an array:

```
> Array.from(new Array(5), () => 'a')
[ 'a', 'a', 'a', 'a', 'a' ]
> Array.from(new Array(5), (x,i) => i)
[ 0, 1, 2, 3, 4 ]
```

If you want to fill an array with a fixed value (first one of the previous two examples) then `Array.prototype.fill()` (see below) is a better choice.

### from() in subclasses of Array

Another use case for `Array.from()` is to convert an array-like or iterable object to an instance of a subclass of `Array`. For example, if you create a subclass `MyArray` of `Array` (subclassing arrays is explained in [1]) and want to convert such an object to an instance of `MyArray`, you simply use `MyArray.from()`. The reason that that works is because constructors inherit from each other in ECMAScript 6 (a super-constructor is the prototype of its sub-constructors).

```
class MyArray extends Array {
  ...
}
let instanceOfMyArray = MyArray.from(anIterable);
```

You can also combine this functionality with mapping, to get a map operation where you control the result's constructor:

```
// from() - determine the result's constructor via the receiver
// (in this case, MyArray)
let instanceOfMyArray = MyArray.from([1, 2, 3], x => x * x);

// map(): the result is always an instance of Array
let instanceOfArray = [1, 2, 3].map(x => x * x);
```

### 1.2. Array.of(...items)

If you want to turn several values into an array, you should always use an array literal, especially since the array constructor doesn't work properly if there is a single value that is a number ([more information](#) on this quirk):

```
> new Array(3, 11, 8)
[ 3, 11, 8 ]
> new Array(3)
[ , , ]
> new Array(3.1)
RangeError: Invalid array length
```

But how are you supposed to turn values into an instance of a sub-constructor of `Array` then? This is where `Array.of()` helps (remember that sub-constructors of `Array` inherit all of `Array`'s methods, including `of()`).

```
class MyArray extends Array {
  ...
}
console.log(MyArray.of(3, 11, 8) instanceof MyArray); // true
console.log(MyArray.of(3).length === 1); // true
```

`Array.of()` is also handy as a function that doesn't have `Array()`'s quirk related to wrapping values in arrays. However, be careful about an `Array.prototype.map()` peculiarity that can trip you up here:

```
> ['a', 'b'].map(Array.of)
[ [ 'a', 0, [ 'a', 'b' ] ],
  [ 'b', 1, [ 'a', 'b' ] ] ]
> ['a', 'b'].map(x => Array.of(x)) // better
[ [ 'a' ], [ 'b' ] ]
> ['a', 'b'].map(x => [x]) // best (in this case)
[ [ 'a' ], [ 'b' ] ]
```

As you can see above, `map()` passes three parameters to its callback, the last two are simply often ignored ([details](#)).

## 2. Prototype methods

Several new methods are available for array instances.

### 2.1. Iterating over arrays

The following methods help with iterating over arrays:

- `Array.prototype.entries()`
- `Array.prototype.keys()`
- `Array.prototype.values()`

The result of each of the aforementioned methods is a sequence of values, but they are not returned as an array; they are revealed one by one, via an iterator. Let's look at an example (I'm using `Array.from()` to put the iterators' contents into arrays):

```
> Array.from([ 'a', 'b' ].keys())
[ 0, 1 ]
> Array.from([ 'a', 'b' ].values())
[ 'a', 'b' ]
> Array.from([ 'a', 'b' ].entries())
[ [ 0, 'a' ],
  [ 1, 'b' ] ]
```

You can combine `entries()` with ECMAScript 6's `for-of` loop [\[2\]](#) and destructuring to conveniently iterate over (index, element) pairs:

```
for (let [index, elem] of [ 'a', 'b' ].entries()) {
  console.log(index, elem);
}
```

Note: this code already works in the current Firefox.

### 2.2. Searching for array elements

`Array.prototype.find(predicate, thisArg?)`

returns the first array element for which the callback predicate returns true. If there is no such element, it returns `undefined`. Example:

```
> [6, -5, 8].find(x => x < 0)
-5
> [6, 5, 8].find(x => x < 0)
undefined
```

`Array.prototype.findIndex(predicate, thisArg?)`

returns the index of the first element for which the callback predicate returns true. If there is no such element, it returns `-1`. Example:

```
> [6, -5, 8].findIndex(x => x < 0)
1
> [6, 5, 8].findIndex(x => x < 0)
-1
```

Both `find*` methods ignore holes [\[3\]](#). The full signature of the callback predicate is:

```
predicate(element, index, array)
```

#### Finding NaN via `findIndex()`

A well-known [limitation](#) of `Array.prototype.indexOf()` is that it can't find `Nan`, because it searches for elements via `==`:

```
> [NaN].indexOf(NaN)
-1
```

With `findIndex()`, you can use `Object.is()` [4] and will have no such problem:

```
> [NaN].findIndex(y => Object.is(NaN, y))
0
```

You can also adopt a more general approach, by creating a helper function `elemIs()`:

```
> function elemIs(x) { return Object.is.bind(Object, x) }
> [NaN].findIndex(elemIs(NaN))
0
```

### 2.3. `Array.prototype.fill(value, start?, end?)`

Fills an array with the given value:

```
> ['a', 'b', 'c'].fill(7)
[ 7, 7, 7 ]
```

Holes [3] get no special treatment:

```
> new Array(3).fill(7)
[ 7, 7, 7 ]
```

Optionally, you can restrict where the filling starts and ends:

```
> ['a', 'b', 'c'].fill(7, 1, 2)
[ 'a', 7, 'c' ]
```

### 3. When can I use the new array methods?

- Some of them are already available in browsers. As usual, check kangax's [ECMAScript 6 compatibility table](#).
- Paul Miller's [es6-shim](#) library has backported them to ECMAScript 5.

Good overview!

1. Instead of "constructor methods", how about the term "static Array functions"? It's a good complement to the term "Array methods", I think.
2. In section 1.2., could you first explicitly define what `Array.of()` does? That section is a bit confusing without the definition.
